## Becs-114.1100 Computational Science / Laskennallinen tiede. Fall 2015.

Assignment 1. Taylor series. Number representation and errors. Due Tuesday 22.09.2015 11 pm.

Web page: https://mycourses.aalto.fi/course/view.php?id=4367 computer = programming task (examples will be given in Python or C) pencil and paper = solve on paper

## **Problem 1.** (computer) (2 points)

Study the following central difference formula:

$$f'(x) \approx \frac{f(x+h) - f(x-h)}{2h}$$

as  $h \to 0$ . Using Taylor's theorem, we obtain that the *truncation error* for this formula is  $-\frac{h^2}{6}f'''(\xi)$  for some  $\xi$  in the interval (x-h,x+h). In a computer, the result is also subject to a *rounding error*. The total error is given by the sum of these two errors.

Write and run a code which computes the approximate values of the truncation error and the total error as a function of h for f(x) = sin(x) at x = 0.5. On the same graph, plot the results showing the rounding error  $(\varepsilon_r)$ , the truncation error  $(\varepsilon_t)$  and the total error  $(\varepsilon = \varepsilon_r + \varepsilon_t)$ . Use log-scale, i.e. plot  $\log_{10} h$  (x-axis) vs.  $\log_{10} |error|$  (y-axis). Analyze the results. (Hint: start with an initial value of h, e.g. h = 0.5, and divide the value of h at each step by some factor, e.g.  $h \leftarrow h/4$ ).

### **Problem 2.** (pencil and paper) (0 points - do not return)

Suppose that you have a floating-point system in which numbers are represented in the following form

$$x = \pm 0.d_1d_2d_3d_4 \times 10^n$$

where the exponent n is a 2-digit (decimal) integer and the normalized mantissa has four digits  $d_1 - d_4$ . Use this system to compute the difference p - q where p = 75640 and q = 4.

# **Problem 3.** (pencil and paper / computer) (2 points)

(a) The harmonic series  $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots$  is known to diverge to  $+\infty$ . The *n*th partial sum approaches  $+\infty$  at the same rate as  $\ln(n)$ . **Euler's constant** is defined to be

$$\gamma = \lim_{n \to \infty} \left[ \sum_{k=1}^{n} \frac{1}{k} - \ln(n) \right] \approx 0.57721$$

Write and test a program that uses a loop of 5000 steps to estimate Euler's constant. Print intermediate answers at every 100 steps. Compare to exact value.

(b) Prove (using pencil and paper) that Euler's constant can also be presented by

$$\gamma = \lim_{m \to \infty} \left[ \sum_{k=1}^{m} \frac{1}{k} - \ln(m + \frac{1}{2}) \right]$$

Write and test a program that uses  $m = 1, 2, 3, \dots, 5000$  to compute  $\gamma$  by this formula. Compare the convergence to the formula given in part (a). For those interested, see D.W.Temple, "A quicker convergence to Euler's constant", Am. Math. Monthly 100, 468 (1993).

## **Problem 4.** (pencil and paper) (0 points - do not return)

Let us have a floating-point representation in which the numbers x are expressed in the following form

$$x = \pm (0.b_1b_2b_3)_2 \times 2^{\pm m}$$
  $m, b_i = \{0, 1\}$ 

List all positive numbers that are representable using this form. (You can form a table of the mantissa and the exponent bits and convert the combination into base 10 numbers). What if the representation is normed (the first bit  $b_1$  is always 1)?

### **Problem 5.** (2 points) (*computer*)

Using a computer, examine how the computed values of the following functions behave near the point x = 0.

(a) 
$$f_1(x) = \frac{e^x - 1}{x}$$
  
(b)  $f_2(x) = \frac{e^x - e^{-x}}{2x}$ 

(b) 
$$f_2(x) = \frac{e^x - e^{-x}}{2x}$$

In order to avoid *loss of significance* as a result of subtracting almost equal numbers, expand the exponential functions into Taylor series and use the resulting approximation to calculate the values of the functions  $f_1$  and  $f_2$  near zero. Estimate the error of the approximation by using Taylor's theorem on the series expansion of the exponential function  $(f(x) = e^x)$ :

$$f(x) = f(0) + \sum_{i=1}^{n-1} \frac{x^i}{i!} f^{(i)}(0) + R(n)$$

where the error term is

$$R(n) = \frac{x^n}{n!} f^{(n)}(\xi) \qquad 0 \le \xi \le x$$
